CLAIMS

What is claimed is:

1	1. A receiver comprising:
2	antenna selection circuitry to select more than one of a plurality of
3	spatially diverse antennas to receive an orthogonal frequency division
4	multiplexed symbol over a wideband channel comprising a plurality of
5	subchannels; and
6	combining circuitry to combine corresponding frequency domain symbol-
7	modulated subcarriers from the selected antennas to generate combined symbol-
3.	modulated subcarriers for each subchannel of the wideband channel.
l	2. The receiver of claim 1 wherein each subchannel of the wideband
2	channel comprises a plurality of orthogonal frequency division multiplexed
3	subcarriers, and
4	wherein each subcarrier of an associated subchannel has a null at
5	substantially a center frequency of other subcarriers of the associated subchannel
l	3. The receiver of claim 1 wherein the combining circuitry comprises
2	maximum-ratio combining circuitry to combine the corresponding frequency
3	domain symbol-modulated subcarriers of the subchannels, and
1	wherein the combining circuitry comprises maximum-ratio combining
5	circuitry to weight at least some of the frequency domain symbol-modulated
5	subcarriers prior to combining the corresponding frequency domain symbol-
7	modulated subcarriers substantially proportional to signal strength.
l	4. The receiver of claim 1 wherein parallel groups of time domain
2	samples are to be generated from each of the subchannels received by each of the
3	antennas, and
1	wherein the receiver further comprises fast Fourier transform circuitry to
5	perform fast Fourier transforms on the parallel groups of time domain samples.

1	5. The receiver of claim 1 wherein the antenna selection circuitry it so
2	select a first antenna of the plurality of antennas to receive the subchannels of the
3	wideband channel,
4	wherein the antenna selection circuitry is to select a second antenna of the
5	plurality of antennas to further receive the subchannels of the wideband channel,
6	and
7	wherein the antenna selection circuitry is to select the first and the second
8	antennas from the plurality based on an average signal-to-noise ratio of signals in
9	the subchannels.
1	6. The receiver of claim 5 further comprising:
2	low-noise amplifiers to amplify radio-frequency signals of at least both
3	subchannels;
4	downconversion circuitry to downconvert radio-frequency signals for
5	each subchannel received through each antenna; and
6	analog-to-digital conversion circuitry to generate digital signals for each
7	subchannel received through each antenna.
1	7. The receiver of claim 4 wherein the fast Fourier transform circuitry
2	comprises:
3	first fast Fourier transform circuitry to perform a fast Fourier transform
4	on parallel groups of time domain samples of a first subchannel from the first
5	antenna to generate frequency domain symbol-modulated subcarriers of the first
6	subchannel from the first antenna;
7	second fast Fourier transform circuitry to perform a fast Fourier
8	transform on parallel groups of time domain samples of a second subchannel
9	from the first antenna to generate frequency domain symbol-modulated
10	subcarriers of the second subchannel from the first antenna;
11	third fast Fourier transform circuitry to perform a fast Fourier transform
12	on parallel groups of time domain samples of the first subchannel from the
13	second antenna to generate frequency domain symbol-modulated subcarriers of

the first subchannel from the second antenna; and

fourth fast Fourier transform circuitry to perform a fast Fourier transform
on parallel groups of time domain samples of the second subchannel from the
second antenna to generate frequency domain symbol-modulated subcarriers of
the second subchannel from the second antenna

8. The receiver of claim 7 wherein the combining circuitry comprises maximum ratio combining circuitry to combine, for each subcarrier of the first subchannel, the frequency domain symbol-modulated subcarriers provided by the first and third fast Fourier transform circuitry to provide combined frequency domain symbol-modulated subcarriers for the first subchannel, and wherein the maximum-ratio combining circuitry is to combine, for each subcarrier of the second subchannel, the frequency domain symbol-modulated subcarriers provided by the second and fourth fast Fourier transform circuitry to provide combined frequency domain symbol-modulated subcarriers for the second subchannel.

9. The receiver of claim 1 further comprising:

equalizer circuitry to perform separately for the more than one subchannel, a channel equalization on the combined symbol-modulated subcarriers of an associated subchannel provided by the combining circuitry.

10. The receiver of claim 9 further comprising:

subcarrier demappers to demap, after the channel equalization, the combined symbol-modulated subcarriers of each subchannel to generate parallel groups of bits from the subcarriers; and

additional processing circuitry to generate a single decoded bit stream representing the orthogonal frequency division multiplexed symbol from the parallel groups of bits of the more than one subchannel.

11. The receiver of claim 10 wherein the subcarrier demappers are to demap the subcarriers of each subchannel in accordance with individual subcarrier modulation assignments particular to the subchannel to generate the parallel groups of bits.

1	12. A method comprising:
2	selecting at least two antennas from a plurality of antennas to receive
3	more than one subchannel of a wideband channel, the subchannels comprising a
4	plurality of orthogonal frequency division multiplexed subcarriers;
5	combining corresponding frequency domain symbol-modulated
6	subcarriers of the subchannels to generate combined symbol-modulated
7	subcarriers for each subchannel; and
8	processing the combined symbol-modulated subcarriers to demodulate an
9	orthogonal frequency division multiplexed symbol from the more than one
10	subchannel.
1	13. The method of claim 12 further comprising:
2	performing fast Fourier transforms on parallel groups of time domain
3	samples for the subchannels received through each of the antennas,
4	wherein the combining comprises maximum-ratio combining comprising
5	weighting at least some of the frequency domain symbol-modulated subcarriers
6	and proportionally combining the weighted frequency domain symbol-modulated
7	subcarriers of the more than one subchannel, and
8	wherein the proportionally combining comprises combining the
9	frequency domain symbol-modulated subcarriers substantially proportional to
10	their signal strength.
1	14. The method of claim 12 wherein selecting comprises:
2	selecting a first pair of antennas of the plurality of antennas to receive
3	one subchannel of the wideband channel;
4	selecting a second pair of antennas of the plurality of antennas to further
5	receive the one subchannel of the wideband channel; and
6	selecting the first and the second pairs of antennas from the plurality
7	based on a signal-to-noise ratio of signals of the subchannel.
1	15. The method of claim 14 further comprising:
2	amplifying, for each selected antenna, radio-frequency signals of the
3	more than one subchannel

4	individually downconverting the radio-frequency signals separately for
5	each subchannel and received through each antenna; and
6	generating digital signals for each subchannel received through each
7	antenna.
1	16. The method of claim 12 further comprising performing a channel
2	equalization separately for the more than one subchannel on the combined
3	symbol-modulated subcarriers of an associated subchannel.
1	17. The method of claim 16 further comprising:
2	demapping, after performing the channel equalization, the combined
3	symbol-modulated subcarriers of each subchannel to generate parallel groups of
4	bits from the subcarriers; and
5	processing the parallel groups of bits of the more than one subchannel to
6	generate a single decoded bit stream representing the orthogonal frequency
7	division multiplexed symbol.
1	18. The method of claim 17 wherein the demapping comprises
2	demapping the subcarriers of each subchannel in accordance with individual
3	subcarrier modulation assignments particular to the subchannel to generate the
4	parallel groups of bits.
1	19. A receiver comprising:
2	antenna selection circuitry to select one or more of a plurality of spatially
3	diverse antennas to receive an orthogonal frequency division multiplexed symbol
4	over a wideband channel comprising more than one of a plurality of subchannels;
5	and
6	subcarrier demodulators to demodulate frequency domain symbol-
7	modulated subcarriers of the more than one subchannel to generate parallel
8	groups of bits from the subcarriers,
9	wherein the processing circuitry is to generate a single decoded bit stream
10	representing the orthogonal frequency division multiplexed symbol from the

parallel groups of bits of the more than one subchannel.

I	20. The receiver of claim 19 wherein each subchannel of the wideband
2	channel comprises a plurality of orthogonal frequency division multiplexed
3	subcarriers,
4	wherein each subcarrier of an associated subchannel has a null at
5	substantially a center frequency of other subcarriers of the associated subchanne
6	and
7	wherein the antenna selection circuitry selects the one or more antennas
8	from the plurality based on a signal-to-noise ratio of signals of the subchannels.
1	21. The receiver of claim 20 further comprising:
2	downconversion circuitry to individually downconvert radio-frequency
3	signals for each subchannel;
4	analog-to-digital conversion circuitry to generate digital signals for each
5	of the subchannels;
6	processing circuitry to generate parallel groups of time domain samples
7	from the digital signals of each of the subchannels; and
8	fast Fourier transform circuitry to perform fast Fourier transforms on the
9	parallel groups of time domain samples to generate the frequency domain
10	symbol-modulated subcarriers for each of the subchannels for subcarrier
11	demodulation.
1	22. A receiver comprising:
2	radio-frequency circuitry to receive an orthogonal frequency division
3	multiplexed symbol over a subchannel through a plurality of spatially diverse
4	antennas; and
5	maximum-ratio combining circuitry to combine corresponding frequency
6	domain symbol-modulated subcarriers from each of the antennas to generate
7	combined symbol-modulated subcarriers for the subchannel.
1	23. The receiver of claim 22 wherein the subchannel comprises a
2	plurality of orthogonal frequency division multiplexed subcarriers,

3	wherein each subcarrier of an associated subchannel has a null at
4	substantially a center frequency of other subcarriers of the associated subchannel,
5	and
6	wherein the maximum-ratio combining circuitry is to weight the
7	frequency domain symbol-modulated subcarriers prior to combining the
8	corresponding frequency domain symbol-modulated subcarriers substantially
9	proportional to their signal strength.
1	24. The receiver of claim 23 further comprising:
2	processing circuitry to generate parallel groups of time domain samples
3	from signals received by each of the antennas; and
4	fast Fourier transform circuitry to perform fast Fourier transforms on the
5	parallel groups of time domain samples to generate the frequency domain
6	symbol-modulated subcarriers from signals received by each antenna,
7	the processing circuitry to generate a single decoded bit stream
8	representing the orthogonal frequency division multiplexed symbol from the
9	parallel groups of bits of the subchannel received by each antenna.
1	25. A system comprising:
2	a plurality of substantially omnidirectional spatially diverse antennas;
3	antenna selection circuitry to select more than one of the antennas to
4	receive an orthogonal frequency division multiplexed symbol over a wideband
5	channel comprising a plurality of frequency-separated subchannels; and
6	maximum-ratio combining circuitry to combine corresponding frequency
7	domain symbol-modulated subcarriers from the selected antennas to generate
8	combined symbol-modulated subcarriers for each subchannel of the wideband
9	channel.
1	26. The system of claim 25 wherein each subchannel of the wideband
2	channel comprises a plurality of orthogonal frequency division multiplexed

subcarriers,

4	wherein each subcarrier of an associated subchannel has a null at
5	substantially a center frequency of other subcarriers of the associated subchannel,
6	and
7	wherein the maximum-ratio combining circuitry is to weight the
8	frequency domain symbol-modulated subcarriers prior to combining the
9	corresponding frequency domain symbol-modulated subcarriers substantially
10	proportional to the signal strength of an associated subcarrier.
1	27. The system of claim 26 wherein parallel groups of time domain
2	samples are to be generated from each of the subchannels received by each of the
3	antennas,
4	wherein the system further comprises fast Fourier transform circuitry to
5	perform fast Fourier transform on the parallel groups of time domain samples,
6	wherein the antenna selection circuitry is to select a first antenna of the
7	plurality of antennas to receive the subchannels of the wideband channel,
8	wherein the antenna selection circuitry is to select a second antenna of the
9	plurality of antennas to further receive the subchannels comprising the wideband
10	channel,
11	wherein the antenna selection circuitry is to select the first and the second
12	antennas from the plurality based on an average signal-to-noise ratio of signals in
13	the individual subchannels, and
14	wherein the system further comprises:
15	downconversion circuitry to individually downconvert radio-frequency
16	signals for each subchannel and received through each antenna; and
17	analog-to-digital conversion circuitry to generate digital signals for each
18	subchannel received through each antenna.
1	28. A reconfigurable receiver comprising:
2	antenna selection circuitry to select one or more of a plurality of spatially
3	diverse antennas to receive one or more of a plurality of subchannels; and
4	maximum-ratio combining circuitry to combine, when more than one
5	antenna per subchannel is selected, corresponding symbol-modulated subcarrier

of subchannels from different selected antennas.

1	29. The receiver of claim 28 wherein the antenna selection circuitry is to
2	select at least one antenna of the plurality to receive either three or four
3	subchannels when a high-throughput mode is enabled,
4	wherein the antenna selection circuitry is to select up to four of the
5	antennas to receive a single subchannel when an increased-range mode is
6	enabled, and
7	wherein the antenna selection circuitry is to select at least two of the
8	antennas to simultaneously receive two of the subchannels when the increased-
9	range and the high-throughput modes are enabled,
10	wherein the antenna selection circuitry is to select the antennas based on
11	an average signal-to-noise ratio of the subchannels.
1	30. The receiver of claim 29 further comprising up to four single channel
2	pipelines to process signals, wherein
3	when the high-throughput mode is enabled, each single channel pipeline
4	is to process signals from an associated one of the either three of four
5	subchannels,
6	when the increased-range mode is enabled, each single channel pipeline
7	is to process signals of the single subchannel received by an associated one of the
8	selected antennas, and
9	when the increased-range and the high-throughput modes are both
10	enabled, a first single channel pipeline is to process signals of a first subchannel
11	received by a first of the selected antennas, a second single channel pipeline is to
12	process signals of a second subchannel received by the first antenna, a third
13	single channel pipeline is to process signals of the first subchannel received by a
14	second of the selected antennas, and a fourth single channel pipeline is to process
15	signals of the second subchannel received by the second of the selected antennas.
1	31. A machine-readable medium that provides instructions which, when
2	executed by one or more processors, cause said processors to perform operations

comprising:

selecting at least two antennas from a plurality of antennas to receive
more than one subchannel of a wideband channel, the subchannels comprising a
plurality of orthogonal frequency division multiplexed subcarriers;
combining corresponding frequency domain symbol-modulated
subcarriers of the subchannels to generate combined symbol-modulated
subcarriers for each subchannel; and
processing the combined symbol-modulated subcarriers to demodulate ar
orthogonal frequency division multiplexed symbol from the more than one
subchannel.
·
32. The machine-readable medium of claim 31 wherein the instructions,
when further executed by one or more of said processors, cause said processors
to perform operations further comprising:
performing fast Fourier transforms on parallel groups of time domain
samples for the subchannels received through each of the antennas,
wherein the combining comprises maximum-ratio combining comprising
weighting at least some of the frequency domain symbol-modulated subcarriers
and proportionally combining the weighted frequency domain symbol-modulated
subcarriers of the more than one subchannel, and
wherein the proportionally combining comprises combining the
frequency domain symbol-modulated subcarriers substantially proportional to
their signal strength.
33. The machine-readable medium of claim 31 wherein the instructions,
when further executed by one or more of said processors, cause said processors
to perform operations further comprising:
selecting a first pair of antennas of the plurality of antennas to receive the
more than one subchannel of the wideband channel;
selecting a second pair of antennas of the plurality of antennas to further
receive the more than one subchannel of the wideband channel; and
selecting the first and the second pairs of antennas from the plurality

based on a signal-to-noise ratio of signals in the subchannels.
